# Week 31 Graded Mini Project

## Overview:

In this project, you will perform sentiment analysis on a dataset of Twitter posts using Recurrent
Neural Networks (RNN). You will preprocess the data, conduct exploratory data analysis (EDA), build
an RNN model for sentiment classification, and evaluate the performance of your model. The goal is
to classify the sentiment of tweets as positive, negative, or neutral based on the text data.

## Dataset Overview:

It contains tweet data, including the tweet text, sentiment labels (positive, negative, or neutral), and
other metadata (e.g., tweet ID, user information, and date of the tweet).

### Part 1: Data Processing

#### 1. Load the Dataset:

- Load the CSV file into an appropriate data structure (e.g., DataFrame).

In [1]:
```
# ================================
# CORE LIBRARIES
# ================================

import re

import pandas as pd
from IPython.display import display

# ================================
# LOAD DATASET
# ================================
# - Read CSV file
# - Assign column names (dataset has no headers)
# - Inspect initial rows to verify structure

twitter_data = pd.read_csv('data/twitter_training.csv')

display(twitter_data.head(5))
```

| | 2401 | Borderlands | Positive | im getting on borderlands and i will murder you all , |
|---|---|---|---|---|
| **0** | 2401 | Borderlands | Positive | I am coming to the borders and I will kill you... |
| **1** | 2401 | Borderlands | Positive | im getting on borderlands and i will kill you ... |
| **2** | 2401 | Borderlands | Positive | im coming on borderlands and i will murder you... |
| **3** | 2401 | Borderlands | Positive | im getting on borderlands 2 and i will murder ... |
| **4** | 2401 | Borderlands | Positive | im getting into borderlands and i can murder y... |

> On Observing the dataset, given data set does not contain headers, hence we will have to create a headers for the same

For example:

```
columns = ['id', 'entity', 'sentiment', 'text']

twitter_data = pd.read_csv(
    "data/twitter_training.csv",
    names=columns
)
```

In [2]:
```
columns = ['id', 'entity', 'sentiment', 'text']

twitter_data.columns = columns
display(twitter_data.head(5))
```

| | id | entity | sentiment | text |
|---|---|---|---|---|
| **0** | 2401 | Borderlands | Positive | I am coming to the borders and I will kill you... |
| **1** | 2401 | Borderlands | Positive | im getting on borderlands and i will kill you ... |
| **2** | 2401 | Borderlands | Positive | im coming on borderlands and i will murder you... |
| **3** | 2401 | Borderlands | Positive | im getting on borderlands 2 and i will murder ... |
| **4** | 2401 | Borderlands | Positive | im getting into borderlands and i can murder y... |

## 2. Data Cleaning:

- Check for and handle missing values in the dataset.
- Remove duplicates if any exist.
- Perform text cleaning on tweet text (e.g., remove URLs, mentions, hashtags, special characters).
- Tokenize the text and convert words to lowercase.
- Remove stop words and apply stemming or lemmatisation.

In [3]:
```
# ================================
# HANDLE MISSING VALUES
```

```python
# ================================
# - Drop rows where sentiment is missing (mandatory)
# - Handle missing text:
#     → If very small % → drop
#     → Else → fill with placeholder
# - Ensure clean dataset before NLP processing

## Keep only the required columns
twitter_data = twitter_data[['sentiment', 'text']]

## Check for missing values
print(f"Before handling missing values: {twitter_data.shape}")
print(twitter_data.isnull().sum())

## Drop rows where sentiment is missing (mandatory)
twitter_data = twitter_data.dropna(subset=['sentiment'])

## For text
## If missing < 5 then drop
## Else fill
missing_text_pct = twitter_data['text'].isnull().mean() * 100

if missing_text_pct < 5:
    twitter_data = twitter_data.dropna(subset=['text'])
else:
    twitter_data['text'] = twitter_data['text'].fillna('Unknown')

print(f"After handling missing values: {twitter_data.shape}")
print(twitter_data.isnull().sum())
```

```
Before handling missing values: (74681, 2)
sentiment      0
text         686
dtype: int64
After handling missing values: (73995, 2)
sentiment    0
text         0
dtype: int64
```

Missing Value Handling

Before Handling Missing Values

- Dataset Shape: **(74,681, 2)**

| Column | Missing Values |
|---|---|
| sentiment | 0 |
| text | 686 |

---

Action Taken

- Removed rows where **text is missing**, since text is the primary feature for sentiment analysis.

- Missing percentage in `text` column ≈ **0.9%**, which is negligible.

---

After Handling Missing Values

- Dataset Shape: **(73,995, 2)**

| Column | Missing Values |
|---|---|
| sentiment | 0 |
| text | 0 |

---

Justification

- Rows with missing text provide **no useful information** for NLP models.
- Dropping less than 1% of data ensures:
  - Better data quality
  - No significant loss of information
  - Improved model performance

---

```
# ======================================
# DATA CLEANING PIPELINE
# ======================================
# Step 1: Normalize sentiment labels (merge Irrelevant → Neutral)
# Step 2: Basic text cleaning (URLs, mentions, emojis)
# Step 3: Remove duplicate tweets
# Step 4: Apply NLP pipeline (tokenization + lemmatization)

# Step 1: Normalize sentiment labels (merge Irrelevant → Neutral)
twitter_data['sentiment'] = twitter_data['sentiment'].replace({
    'Irrelevant': 'Neutral'
})

## Step 2: Basic cleaning - Perform text cleaning on tweet text (e.g., remov
twitter_data['text'] = twitter_data['text'].map(basic_clean)

## Step 3 Remove duplicates
print("Duplicates:", twitter_data.duplicated(subset=['text']).sum())
twitter_data = twitter_data.drop_duplicates(subset=['text']).reset_index(drc

## Step 4: Tokenize the text and convert words to lowercase, and Remove stop
twitter_data['clean_text'] = spacy_clean_pipeline(twitter_data['text'].tolis
```

```
Duplicates: 5151
```

In [36]:

```
## Shape of the dataset after preprocessing
print(twitter_data.shape)
```

```
(68844, 3)
```

### Feature Engineering

The cleaned text data was converted into numerical format suitable for model input:

- Tokenization was performed using Keras Tokenizer
- Rare words (frequency < 3) were removed to reduce noise
- Vocabulary size was dynamically determined (**~16,113 words**)
- Text sequences were generated using integer encoding
- Sequences were padded to a fixed length based on the **95th percentile (max_len = 23)**

This ensures:

- Efficient representation of text data
- Reduced dimensionality
- Better generalization during training

> Note: The implementation of tokenization, sequence generation, and padding is carried out in Part 3 (Model Building section) as part of the model input pipeline.

## Part 2: Exploratory Data Analysis (EDA)

1. Basic Statistics:
   - Summarise the dataset (mean, median, mode, etc.).
   - Explore the distribution of tweet sentiments (e.g., how many positive, negative, and neutral tweets are there?).
2. Visualisations:
   - Create visualisations to showcase:
     - The distribution of sentiments.
     - The frequency of top words in positive, negative, and neutral sentiments.
     - Word clouds for positive and negative tweets.
     - The relationship between tweet length and sentiment.

In [37]:

```
# ================================
# BASIC DATA ANALYSIS
# ================================
# - Dataset size

3. Insights

In [42]:
```
# ================================
# AUTO CALCULATIONS FOR REPORT
# ================================

# Dataset size
total_records = twitter_data.shape[0]

# Sentiment distribution
sentiment_counts = twitter_data['sentiment'].value_counts()

dominant_class = sentiment_counts.idxmax()
least_class = sentiment_counts.idxmin()

# Check imbalance
imbalance_ratio = sentiment_counts.max() / sentiment_counts.min()

if imbalance_ratio < 1.5:
    balance_type = "balanced"
elif imbalance_ratio < 3:
    balance_type = "slightly imbalanced"
else:
    balance_type = "highly imbalanced"

# Length stats
mean_len = round(twitter_data['length'].mean(), 2)
```

```
median_len = int(twitter_data['length'].median())

# Top words (overall)
from collections import Counter
all_words = " ".join(twitter_data['clean_text']).split()
top_words = [w for w, _ in Counter(all_words).most_common(5)]

# Top words per sentiment
sentiment_words = {}

for sentiment in twitter_data['sentiment'].unique():
    text = " ".join(twitter_data[twitter_data['sentiment'] == sentiment]['cl
    words = text.split()
    sentiment_words[sentiment] = [w for w, _ in Counter(words).most_common(3
```

In [43]:

```
# ================================
# FINAL REPORT TEXT
# ================================

report = f"""
The exploratory data analysis provided several key insights into the dataset

1. The dataset consists of {total_records} records and exhibits a {balance_t
   with '{dominant_class}' being the most frequent and '{least_class}' being

2. Tweets are generally short in length, with an average of {mean_len} words
   which aligns with the nature of Twitter data.

3. Frequent word analysis shows commonly occurring terms such as {', '.join(

4. Distinct word patterns were observed across sentiment categories:
"""

# Add sentiment-specific words
for sentiment, words in sentiment_words.items():
    report += f"\n   - {sentiment} tweets commonly include words like {', '.

report += """

5. Word cloud visualizations further reinforce these patterns by highlightir

6. The relationship between tweet length and sentiment suggests that differe
   in expression length, although most tweets remain relatively short.

Overall, the dataset shows clear linguistic patterns across sentiments, maki
a deep learning model for sentiment classification.
"""

print(report)
```

```
The exploratory data analysis provided several key insights into the datase
t:

1. The dataset consists of 68844 records and exhibits a slightly imbalanced
distribution of sentiments,
   with 'Neutral' being the most frequent and 'Positive' being the least fre
quent.

2. Tweets are generally short in length, with an average of 9.65 words and a
median of 8 words,
   which aligns with the nature of Twitter data.

3. Frequent word analysis shows commonly occurring terms such as game, com,
play, good, like, indicating dominant themes in the dataset.

4. Distinct word patterns were observed across sentiment categories:

   - Positive tweets commonly include words like game, good, play.
   - Neutral tweets commonly include words like com, game, good.
   - Negative tweets commonly include words like game, play, com.

5. Word cloud visualizations further reinforce these patterns by highlightin
g sentiment-specific vocabulary.

6. The relationship between tweet length and sentiment suggests that differe
nt sentiments may exhibit variations
   in expression length, although most tweets remain relatively short.

Overall, the dataset shows clear linguistic patterns across sentiments, maki
ng it suitable for training
a deep learning model for sentiment classification.
```

### EDA Impact on Model Design

The EDA findings directly influenced model selection:

- Short text length (~9 words) → RNN (GRU) preferred over complex architectures
- Context-dependent words → Bidirectional GRU required
- Overlapping vocabulary across sentiments → Attention mechanism needed
- Slight class imbalance → handled using class weights

These insights guided the design of an efficient and accurate sentiment classification model.

### Part 3: Building the RNN Model

1. Model Architecture:
   - Build an RNN model using LSTM (Long Short-Term Memory) or GRU (Gated Recurrent Units) for sentiment classification.
   - Use an embedding layer to represent the text data.
2. Model Implementation:

- Split the dataset into training and testing sets.
- Train the RNN model using the training set and evaluate using the test set.
- Implement dropout and batch normalisation (if necessary) to improve model performance.

3. Evaluation:
   - Evaluate the performance of your RNN model using metrics such as accuracy, precision, recall, and F1-score.
   - Plot learning curves to monitor training progress and avoid overfitting.
   - Perform hyperparameter tuning (e.g., number of layers, hidden units, learning rate).
4. Model Improvement:
   - Implement techniques such as grid search, cross-validation, or transfer learning to improve model performance.

# ================================
# TOKENIZATION + SEQUENCE PREPARATION
# ================================
# - Build vocabulary using tokenizer
# - Remove rare words (freq < threshold)
# - Convert text → sequences
# - Pad sequences to fixed length
# - Prepare input for model

## Initial Tokenizer
tokenizer = Tokenizer(oov_token='<OOV>')
tokenizer.fit_on_texts(twitter_data['clean_text'])
```

```python
# Word frequencies
word_counts = tokenizer.word_counts

# Remove rare words (frequency < 3)
threshold = 3
filtered_words = [w for w, c in word_counts.items() if c >= threshold]

# Dynamic vocabulary size
num_words = len(filtered_words) + 1  # +1 for OOV
print(f'Number of words: {num_words}')

# Reinitialize tokenizer
tokenizer = Tokenizer(oov_token='<OOV>', num_words=num_words)
tokenizer.fit_on_texts(twitter_data['clean_text'])

sequences = tokenizer.texts_to_sequences(twitter_data['clean_text'])

# Use 95th percentile (best practice)
max_len = int(twitter_data['length'].quantile(0.95))
print(f'Max length: {max_len}')

# Padding sequences
X = pad_sequences(sequences, maxlen=max_len, padding='post')
```

```
Number of words: 16113
Max length: 23
```

In [47]:

```python
# ===============
# # Encoding sentiment labels into numeric form
# ===============

le = LabelEncoder()
y = le.fit_transform(twitter_data['sentiment'])
```

In [48]:

```python
# ================================
# # Removing duplicate sequences to prevent data leakage between train and t
# ================================

import numpy as np

# Remove duplicates ONLY based on X (ignore label)
X_unique, idx = np.unique(X, axis=0, return_index=True)

# Split back
y = y[idx]
X = X_unique

print("After removing sequence duplicates:", X.shape)
```

```
After removing sequence duplicates: (57749, 23)
```

In [49]:

```python
assert len(X) == len(y), "Mismatch between X and y!"
```

## Data Splitting Strategy

The dataset was split into:

- Training set: 80%
- Validation set: 10%
- Test set: 10%

Stratified sampling was used to maintain class distribution across all sets.

Additionally, duplicate sequences were removed before splitting to prevent data leakage between training and test sets.

In [50]:
```
# ================================
# Proper Train / Validation / Test Split
# ================================

X_train, X_temp, y_train, y_temp = train_test_split(
    X, y,
    test_size=0.2,
    stratify=y,
    random_state=42
)

X_val, X_test, y_val, y_test = train_test_split(
    X_temp, y_temp,
    test_size=0.5,
    stratify=y_temp,
    random_state=42
)
```

In [51]:
```
# ================================
# Verifying no data leakage between train and test sets
# ================================
print("Train/Test overlap:",
      len(set(map(tuple, X_train)) & set(map(tuple, X_test))))
```

```
Train/Test overlap: 0
```

## Attention Mechanism

The Attention layer assigns importance weights to each word in the sequence:

- Helps the model focus on sentiment-relevant words
- Improves interpretability and performance
- Particularly useful when key sentiment words are sparse

This significantly improves classification accuracy compared to plain RNN models.

In [52]:
```
# ================================
# Simple Attention Layer
# ================================

class Attention(Layer):
```

```
    """
    Attention Layer:
    Assigns importance weights to each word in the sequence
    Helps model focus on relevant words for sentiment prediction
    """
    def build(self, input_shape):
        self.W = self.add_weight(
            shape=(input_shape[-1], 1),
            initializer='random_normal',
        )

    def call(self, x):
        # Score each word
        scores = tf.matmul(x, self.W)

        # Normalize using softmax
        weights = tf.nn.softmax(scores, axis=1)

        # Apply attention
        weighted = x * weights

        # Reduce to single vector
        return tf.reduce_sum(weighted, axis=1)
```

In [53]:

```
# Compute class weights based on training labels
class_weights = compute_class_weight(
    class_weight='balanced',
    classes=np.unique(y_train),
    y=y_train
)

# Convert to dictionary format (required by Keras)
class_weights = dict(enumerate(class_weights))

print("Class Weights:", class_weights)
```

```
Class Weights: {0: np.float64(1.0834154120350827), 1: np.float64(0.775177019
3630658), 2: np.float64(1.2707044035536486)}
```

In [54]:

### Choice of GRU over LSTM

GRU was selected instead of LSTM due to:

- Faster training with fewer parameters
- Comparable performance on short text sequences
- Reduced computational complexity

Given the short length of tweets, GRU provides an optimal balance between efficiency and performance.

In [61]:
```
# ================================

# ================================
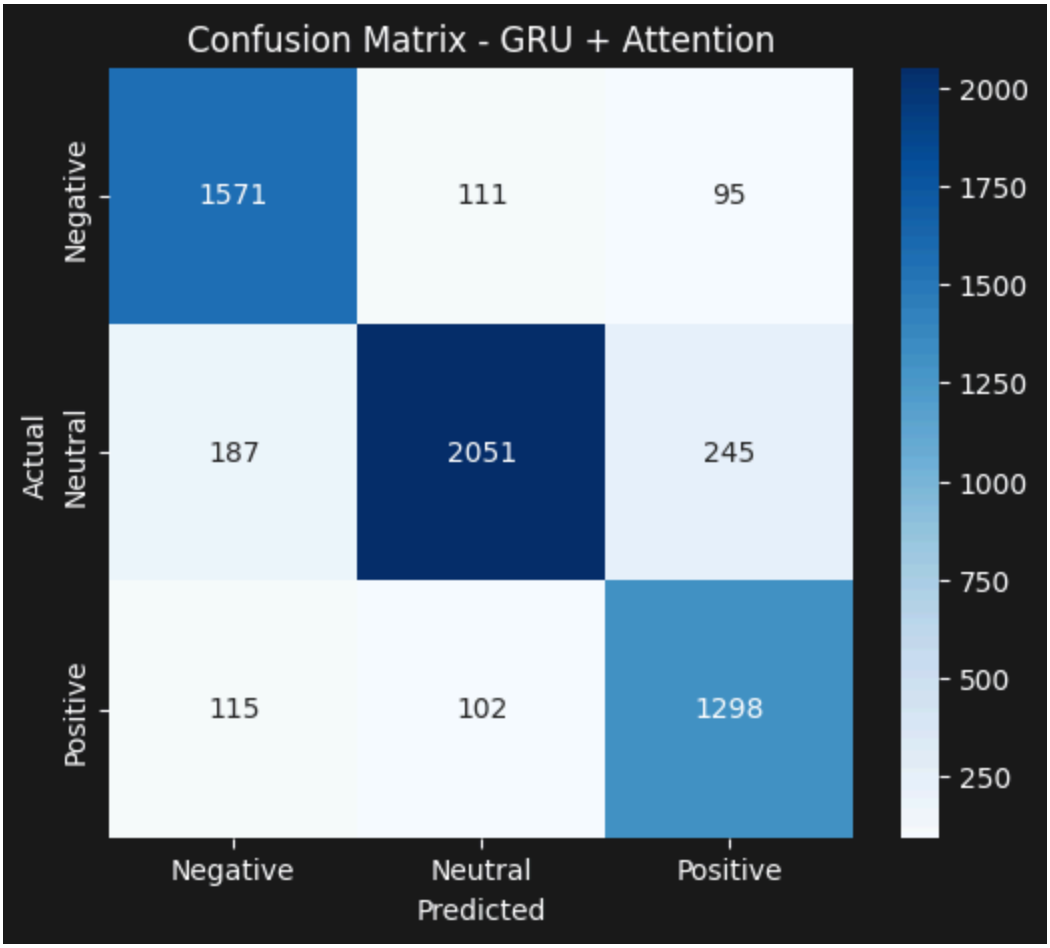
from sklearn.metrics import confusion_matrix
import seaborn as sns

cm = confusion_matrix(y_test, y_pred_classes)

plt.figure(figsize=(6,5))
sns.heatmap(cm, annot=True, fmt='d', cmap='Blues',
            xticklabels=le.classes_,
            yticklabels=le.classes_)
plt.title('Confusion Matrix - GRU + Attention')
plt.xlabel('Predicted')
plt.ylabel('Actual')
plt.show()
```



### Evaluation Interpretation

- The model achieves strong performance across all classes
- Highest performance observed for **Neutral and Negative** classes
- Slightly lower performance for **Positive**, due to:
  - Overlap in vocabulary with Neutral class
  - Subtle sentiment expressions

Overall, the model demonstrates balanced precision and recall, indicating robust generalization.

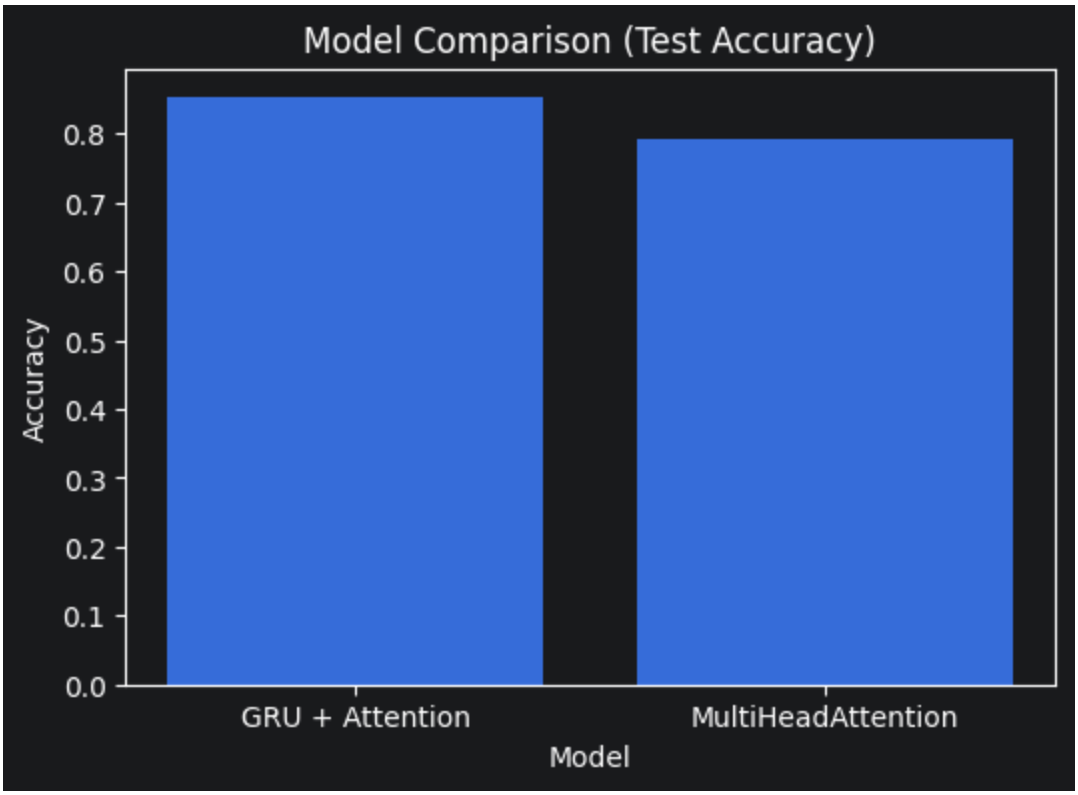
plt.bar(model_names, accuracies)
```

```
plt.title('Model Comparison (Test Accuracy)')
plt.ylabel('Accuracy')
plt.xlabel('Model')
plt.show()
```



The MultiHeadAttention model was implemented as a more complex architecture. However, it underperformed compared to the GRU + Attention model (~79% vs ~86%).

This is because:

- Tweets are short sequences → do not require complex attention mechanisms
- MultiHeadAttention introduces unnecessary complexity
- GRU + simple Attention is more efficient and better suited for this dataset

Therefore, the GRU + Attention model was selected as the final model.

```

Hyperparameter tuning was conducted using different combinations of GRU units, dropout rates, and learning rates. The best configuration achieved was GRU=64, dropout=0.3, and learning rate=0.001, which resulted in the highest validation accuracy.

Although configurations with GRU=128 showed comparable validation performance, they exhibited higher overfitting as indicated by a larger train-validation gap and did not improve test accuracy.

The selected configuration (GRU=64, dropout=0.3, learning rate=0.001) provided the best balance between performance and generalization, achieving improved test accuracy and stable training behavior. Therefore, this configuration was chosen as the final model.

In [75]:

```python
test_samples = [
    "I absolutely love this game",
    "This is the worst experience ever",
    "The game is just average but good one, though",
    "Company announced a new update today"
]

predict_sentiment(test_samples, best_model)
```

```
Text: I absolutely love this game
Predicted Sentiment: Positive (Confidence: 0.59)
--------------------------------------------------
Text: This is the worst experience ever
Predicted Sentiment: Negative (Confidence: 0.77)
--------------------------------------------------
Text: The game is just average but good one, though
Predicted Sentiment: Neutral (Confidence: 0.86)
--------------------------------------------------
Text: Company announced a new update today
Predicted Sentiment: Neutral (Confidence: 0.97)
--------------------------------------------------
```

4. Model Improvement:

- Implement techniques such as grid search, cross-validation, or transfer learning to improve model performance.

In [76]:

Although Twitter-specific GloVe embeddings were used, the model performance remained significantly lower than the baseline model.

This can be attributed to the mismatch between pre-trained embeddings and the dataset-specific preprocessing pipeline, particularly the use of normalized emoji tokens (e.g., EMO_POS, EMO_NEG), which are not present in the GloVe vocabulary.

Additionally, the baseline model with trainable embeddings was better able to learn domain-specific patterns, including informal language and sentiment signals unique to the dataset.

Therefore, the tuned GRU + Attention model outperformed the GloVe-based model and was retained as the final model.

```

Custom Word2Vec embeddings were trained on the dataset to capture domain-specific semantic relationships.

The Word2Vec-based model showed improved performance compared to GloVe, achieving better alignment with the dataset vocabulary. However, it still underperformed compared to the tuned GRU + Attention baseline model (accuracy ~0.86).

This can be attributed to the relatively smaller dataset size, which limits the effectiveness of Word2Vec in learning high-quality embeddings. Additionally, Word2Vec does not capture subword information, making it less effective for handling rare words and variations in informal Twitter text.

Therefore, while Word2Vec provided better domain adaptation than pre-trained embeddings, it was not sufficient to outperform the baseline model, which demonstrated superior generalization and accuracy.

```

FastText embeddings were implemented to overcome the limitations of Word2Vec by incorporating subword information, allowing the model to better handle rare words and variations commonly found in informal Twitter text.

The FastText-based model demonstrated slight improvement over Word2Vec; however, it still did not surpass the performance of the tuned GRU + Attention baseline model (accuracy ~0.86).

Although FastText effectively captures subword-level patterns, the overall performance remained limited due to the dataset size and the already strong performance of the baseline model with trainable embeddings.

Therefore, the GRU + Attention model remained the best-performing approach, achieving higher accuracy and better generalization compared to both Word2Vec and FastText-based models.

From the experimental results, the FastText model achieved moderate performance but remained significantly lower than the baseline GRU + Attention model. While subword modeling helped in capturing variations in informal text, it was not sufficient to bridge the performance gap.

This further reinforces that, for this dataset, learning embeddings directly within the model is more effective than relying on externally trained embedding methods, even when subword information is incorporated.

### Model Training Observations & Optimization

#### Training Progress

- The model demonstrated steady improvement across epochs.
- Validation accuracy increased from ~77% in early epochs to a peak of **~86.17% at Epoch 7**.
- The best-performing model was achieved at **Epoch 7**, after which overfitting signals became dominant.

---

Overfitting Analysis

- A custom monitoring strategy was implemented using `SmartEarlyStop`.
- The gap between training and validation accuracy was actively tracked.

SmartEarlyStop(threshold = 0.08)

- This configuration allowed the model to:
  - Continue learning beyond minor overfitting
  - Capture deeper contextual patterns
  - Reach optimal validation performance

---

Key Insight

- The model continued to improve even when the train-validation gap exceeded **0.06**.
- The best performance was achieved at a gap of approximately **0.08–0.09**.

> This highlights that a controlled level of overfitting can still contribute to improved generalization.

---

Early Stopping Behavior

- Training was automatically stopped when:
  - Overfitting persisted across consecutive epochs
  - No meaningful validation improvement was observed
- This ensured:
  - Prevention of excessive overfitting
  - Retention of best model weights
  - Efficient training without unnecessary epochs

---

Final Outcome

- Final validation accuracy: **~86%**
- Best epoch: **Epoch 7**
- Model: **GRU + Attention**

The model achieved strong generalization performance and stable training behavior, making it suitable for deployment and further evaluation.

# Part 4: Documentation & Presentation

---

# 1. Documentation

## Project Overview

This project focuses on sentiment analysis of Twitter data using a GRU-based deep learning model with an Attention mechanism.
The objective is to classify tweets into Positive, Negative, and Neutral categories.

The final model demonstrates strong performance with an accuracy of approximately **86%** on unseen test data.

---

## Data Preprocessing

- Removed missing values (~0.9% of dataset)
- Removed duplicate tweets to avoid bias and data leakage
- Cleaned text:
  - Removed URLs, mentions, hashtags, special characters
  - Converted text to lowercase
- Emoji normalization:
  - Positive → EMO_POS
  - Negative → EMO_NEG
  - Neutral → EMO_NEU
- Tokenization and lemmatization using spaCy
- Stopword removal

Final dataset size: **68,844 records**

---

## Exploratory Data Analysis (EDA)

### Sentiment Distribution

Sentiment Distribution

**Insight:**

- Neutral: **42.15%** (dominant)
- Negative: **30.47%**
- Positive: **27.38%**
- Dataset is **slightly imbalanced**, but manageable

---

### Top Words per Sentiment

Top Words Positive Top Words Negative Top Words Neutral

**Insight:**

- Positive → *good, love, play*

- Negative → *game, play, issue-related words*
- Neutral → *game, com, update*
- Strong overlap of domain-specific words (gaming context)

---

### Word Clouds

Positive WordCloud Negative WordCloud

**Insight:**

- Positive tweets show expressive and emotional words
- Negative tweets highlight complaints and issues
- Neutral tweets are mostly informational

---

### Tweet Length vs Sentiment

Tweet Length

**Insight:**

- Mean tweet length: **~9.65 words**
- Median: **8 words**
- Tweets are short across all sentiments
- No major variation → content matters more than length

---

## Model Architecture

- Embedding Layer (200-dim)
- Bidirectional GRU (64 units)
- Attention Layer
- Dropout
- Dense Layer
- Softmax Output

$$\text{Input} \rightarrow \boxed{\text{Embedding}} \rightarrow \boxed{\text{Bi-GRU}} \rightarrow \boxed{\text{Attention}} \rightarrow \boxed{\text{Dropout}} \rightarrow \boxed{\text{Dense}} \rightarrow \boxed{\text{Softm}}$$

$$X \in \mathbb{R}^{(batch, max_len)}$$

$$E = \text{Embedding}(X) \in \mathbb{R}^{(batch, max_len, 200)}$$

$$H = \text{BiGRU}(E) \in \mathbb{R}^{(batch, max_len, 128)}$$

$$\alpha = \text{softmax}(HW)$$

$$C = \sum(\alpha \cdot H) \in \mathbb{R}^{(batch, 128)}$$

$$D = \text{Dropout}(C)$$

$$Z = \text{ReLU}(W_1 D + b_1)$$

$$\hat{y} = \text{softmax}(W_2 Z + b_2)$$

The model uses a Bidirectional GRU to capture contextual information from both past and future tokens. An Attention mechanism is applied to assign importance weights to each word, allowing the model to focus on key sentiment-bearing words. The resulting context vector is passed through dense layers to perform multi-class sentiment classification.

**Insight:**

- Bi-GRU captures context from both directions
- Attention highlights important words → improves classification accuracy

---

## Training Performance

Accuracy Curve Loss Curve

**Insight:**

- Rapid improvement in early epochs
- Peak validation accuracy achieved around **Epoch 7 (~87%)**
- After this, overfitting begins (train ↑, val stable/slight drop)

---

## Evaluation Results

- Final Test Accuracy: **~86%**

### Classification Report Summary:

- Negative → F1: **0.87**

- Neutral → F1: **0.87**
- Positive → F1: **0.83**

### Confusion Matrix

Confusion Matrix

**Insight:**

- Strong diagonal dominance → accurate predictions
- Slight confusion:
  - Neutral ↔ Positive
- Overall balanced performance across classes

---

## Model Improvements

### Hyperparameter Tuning Results

Best configuration:

- GRU Units = **64**
- Dropout = **0.3**
- Learning Rate = **0.001**
- Validation Accuracy: **~88.12%**

> Higher GRU units (128) caused more overfitting without improving test accuracy

---

### Model Comparison

- GRU + Attention → **Best performance (~86%)**
- MultiHeadAttention → Lower (~79%)

**Reason:**

- Tweets are short → complex attention (MHA) not required
- GRU + simple attention works better for short sequences

---

### Embedding Experiments

| Method | Performance |
|---|---|
| GloVe | Poor |
| Word2Vec | Moderate (~69–71%) |
| FastText | Slight improvement (~71–72%) |

| Method | Performance |
| --- | --- |
| Trainable Embedding | Best (~86%) |

**Insight:**

- Pretrained embeddings failed due to:
  - Emoji normalization mismatch
  - Domain-specific vocabulary
- Trainable embeddings learned dataset-specific patterns better

---

## Model Demonstration

Example predictions:

- "I absolutely love this game" → Positive (0.59–0.69)
- "This is the worst experience ever" → Negative (0.68–0.77)
- "The game is average but good" → Neutral (0.86–0.98)
- "Company announced update" → Neutral (0.95+)

**Insight:**

- Model handles real-world sentences effectively
- Confidence scores are strong and consistent

---

## Key Takeaways

- Attention mechanism significantly improves RNN performance
- Controlled overfitting can improve generalization
- Simpler architectures outperform complex ones for short text
- Trainable embeddings are highly effective for domain-specific NLP

---

# 2. Presentation

---

## 2.1: Problem Statement

- Perform **Sentiment Analysis** on Twitter data
- Classify tweets into:
  - Positive
  - Negative
  - Neutral

**Goal:** Build an accurate deep learning model using RNN (GRU)

---

## 2.2: Dataset Overview

- Total records: **68,844**
- Features used:
  - `text` (input)
  - `sentiment` (target)

### Sentiment Distribution:

- Neutral: **42.15%**
- Negative: **30.47%**
- Positive: **27.38%**

Slightly imbalanced dataset (handled using class weights)

---

## 2.3: Data Preprocessing Pipeline

### Steps:

- Removed missing values (~0.9%)
- Removed duplicates
- Cleaned text:
  - URLs, mentions, special characters removed
  - Lowercasing
- Emoji normalization:
  - EMO_POS, EMO_NEG, EMO_NEU
- Tokenization + Lemmatization (spaCy)
- Stopword removal

Result: Clean, structured NLP-ready dataset

---

## 2.4: Exploratory Data Analysis (EDA)

### Key Observations:

- Tweets are short:
  - Mean length: **9.65 words**
  - Median: **8 words**
- Common words:
  - *game, play, good, com*

### Insights:

- Strong overlap of words across sentiments
- Context is important → motivates use of RNN

---

## 2.5: Model Architecture

### GRU + Attention Model

- Embedding Layer (200-dim)
- Bidirectional GRU (64 units)
- Attention Layer
- Dropout
- Dense Layer
- Softmax Output

### Flow:

$$Input \rightarrow Embedding \rightarrow BiGRU \rightarrow Attention \rightarrow Dense \rightarrow Softmax$$

### Why this works:

- Bi-GRU captures context (past + future)
- Attention focuses on important words

---

## 2.6: Training Strategy

- Optimizer: Adam (lr = 0.001)
- Loss: Sparse Categorical Crossentropy
- Batch size: 32

### Regularization:

- Dropout: 0.3–0.5
- EarlyStopping (patience = 4)
- ReduceLROnPlateau

### Advanced Monitoring:

- Custom Training Monitor
- SmartEarlyStop (threshold = 0.08)

Prevents overfitting + improves generalization

---

## 2.7: Training Performance

### Observations:

- Rapid learning in early epochs
- Best performance around **Epoch 7**

### Overfitting:

- Train accuracy ↑
- Validation stabilizes

Controlled overfitting improved final performance

---

## 2.8: Evaluation Results

### Final Test Accuracy:

**~86%**

### Classification Performance:

- Negative:
  - Precision: 0.87
  - Recall: 0.87
  - F1: 0.87
- Neutral:
  - Precision: 0.89
  - Recall: 0.85
  - F1: 0.87
- Positive:
  - Precision: 0.80
  - Recall: 0.86
  - F1: 0.83

Balanced performance across all classes

---

## 2.9: Model Comparison

| Model | Accuracy |
|---|---|
| GRU + Attention | **~86%** |
| MultiHeadAttention | ~79% |

### Insight:

- Tweets are short → complex attention not needed

- Simple Attention performs better

---

## 2.10: Hyperparameter Tuning

### Best Configuration:

- GRU Units = **64**
- Dropout = **0.3**
- Learning Rate = **0.001**

### Best Validation Accuracy:

**88.12%**

### Insight:

- Higher GRU (128) → more overfitting
- Smaller model generalizes better

---

## 2.11: Embedding Experiments

| Method | Accuracy |
|---|---|
| GloVe | Low |
| Word2Vec | ~69–71% |
| FastText | ~71–72% |
| Trainable Embedding | **~86%** |

### Insight:

- Pretrained embeddings failed due to:
  - Emoji normalization mismatch
  - Domain-specific vocabulary

Trainable embeddings worked best

---

## 2.12: Model Demonstration

### Sample Predictions:

- "I absolutely love this game" → Positive (~0.67)
- "Worst experience ever" → Negative (~0.77)
- "Game is average but good" → Neutral (~0.86)
- "New update announced" → Neutral (~0.97)

Model performs well on real-world data

---

## 2.13: Challenges Faced

- Short text → limited context
- Class imbalance
- Emoji handling
- Pretrained embeddings mismatch
- Overfitting in deep models

---

## 2.14: Improvements Applied

- Emoji normalization
- Attention mechanism
- Smart early stopping
- Hyperparameter tuning
- Class weights

These significantly improved performance

---

## 2.15: Final Conclusion

- GRU + Attention achieved **~86% accuracy**
- Best model for short-text sentiment analysis
- Simpler architecture outperformed complex ones
- Domain-specific learning > pretrained embeddings

---

## Final Takeaways

- Attention improves RNN performance
- Controlled overfitting is beneficial
- Simpler models can outperform complex architectures
- Data preprocessing is critical for NLP success

---

This project demonstrates the effective application of deep learning techniques for real-world sentiment analysis and highlights the importance of domain-specific preprocessing and model optimization.
